*Anglostatin: a novel anglogenesis inhibitor that mediates the suppression of metastases by a Lewis lung carcinoma.";

cell 79:315-328(1994).

-!- FUNCTION: PLASMIN DISSOLVES THE FIBRIN OF BLOOD CLOTS AND ACTS A PROPEDLYTIC RACTOR IN A VARIETY OF OTHER PROCESSES INCLUDING EMBRYONIC DEVELOPMENT, TISSUE REMOBELING, TUMOR INVASION, AND INFLAMMATION: IN OVULATION IT WEAKENS THE WALLS OF THE GRAAFIAN FOLLICLE. IT ACTIVATES THE UNKNINGEN ACTIVATED ACTIVATES AND SEVERAL COMPLEMENT ZYMOGENS, SUCH ACTIVATES PROPERIES THE REMOBELING, THROMBOSPONDIN, AS CI AND G5. IT CLEAVES FIBRIN, FIBRONECTIN, THROMBOSPONDIN,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            AS C1 AND C5. IT CLEAVES FIBKIN, FIDNOMOLIN, LAMININ AND VON WILLEBRAND FACTOR.
FUNCTION: ANGLOSTATIN IS AN ANGIOGENESIS INHIBITOR THAT BLOCKS NEOVASCULARIZATION AND GROWTH OF EXPERIMENTAL PRIMARY AND

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         EXZYME REGULATION: CONVERTED INTO PLASMIN BY PLASMINOGEN ACTIVATORS, BOTH PLASMINOGEN AND ITS ACTIVATOR BEING BOUND TO ACTIVATORS, BOTH PLASMINOGEN AND ITS ACTIVATOR BEING BOUND TO MISCELLANDEDUS: PLASMIN IS INACTIVATED BY ALPHA-2-ANTIPLASMIN IMMEDIATELY AFTER DISSOCIATION FROM THE CLOT.

MISCELLANDEDUS: IN THE PRESENCE OF THE INHIBITOR, THE ACTIVATION INVOLVES ONLY CLERVAGE AFTER ARG-580, RESULTING IN 2 CHAINS HELD TOGETHER BY 2 DISULFIDE BONDS: WITHOUT THE INHIBITOR, THE STINGLARTY: BELONGS TO PEPTIDASE FAMILY SI. PLASMINOGEN SUBFAMILY. SIMILARITY: CONTAINS 5 KRINGLE DOMAINS.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        PARLICES 13.

19 Biol. Chem. 264:5957-5965(1989).

1- FUNCTION: PLASMIN DISSOLVES THE FIBRIN OF BLOOD CLOTS AND ACTS AS A PROTEOLYTIC FACTOR IN A VARIETY OF OTHER PROCESSES INCLUDING EMBRYONIC DEVELOPMENT. TISSUE REMODELING, TUWOR INVASION, AND INFLAMMATION; IN OVULATION IT WEAKENS THE WALLS OF THE GRAAFTAN FOLLICE. IT ACTIVATES THE UROKINASE-TYPE PLASMINOGEN ACTIVATOR, COLLAGENASES AND SEVERAL COMPLEMENT ZYMOGENS, SUCH AS C1 AND C5. IT CLEAVES FIBRIN, FIBRONECTIN, THROMBOSPONDIN, LAMININ AND YON WILLEBRAND FACTOR.

-1- CATALITY: PERFERENTIAL CLEAVES FIBRIN, FIBRONECTIN, THROMBOSPONDIN, INDIANCES ESCHOOL CONVEXES FIBRIN TO CONVEXE FIBRIN TO SOLUBLE AND SECTIVATY: PERFERENTIAL CLEAVES FIBRIN THROMBOSPONDIN, LAMININ SELECTIVITY: PERFERENTIAL CLEAVES FIBRIN FACTOR.
                                                                                                                           440
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  SEQUENCE FROM N.A.

DISEASE: Elevated plasma concentrations of apo(a) and its naturally occurring proteolytic fragments are correlated with atherosclerosis. Homology with plasminogen kringles IV and V is thought to underlie the atherogenicity of the protein, because the fragments are competing with plasminogen for fibrin(ogen) binding. MISCELLANEOUS: Apo(a) is known to be proteolytically clasaved, leading to the formation of the so called mini-Lp(a). Apo(a) fragments accumulate in atherosclerotic lesions, where they may promote thrombogenesis. O-glycosylation may limit the extent of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     PTM: N- and O-glycosylated. The N-glycans are complex biantennary structures present in either a mono- or disialylated state. The O-glycans are mostly (80%) represented by the monosialylated core type I structure, NeuNAcalpha2-3Galbeta1-3GalNAc, with smaller

                                                            DISEASE: Elevated plasma concentrations of apo(a) and its naturally occurring proteolytic fragments are correlated with atherosclerosis. Homology with plasminogen kringles IV and V is thought to underlie the atherosenicity of the protein, because the fragments are competing with plasminogen for fibrin(ogen) binding. MRSCELLAMBROOS: Apo(a) is known to be proteolytically cleaved, leading to the formation of the so called mini-Lp(a). Apo(a) fragments accumulate in atherosclerotic lesions, where they may promote thrombogenesis. O-glycosylation may limit the extent of proteolytic fragmentation (By similarity).

SIMILARITY: BELONGS TO PEPTIDASE FAMILY SI. PLASMINOGEN SUBFAMILY. SIMILARITY: CONTAINS AT LEAST 10 KRINGLE DOMAINS.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ENKDYIRNCIIGKGRSYKGTVSITKSGIKCQPWSSMIPHEHSFLPSSYRGKDLQENYCRN 148

Towth factor binds the c-Met receptor and induces cell dissociation but not mitogenesis.";
Proc. Natl. Acad. Sci. U.S.A. 89:11574-11578(1992).
C -!- FUNCTION: HGF IS A POTENT MITOGEN FOR MATURE PARENCHYMAL HEPATOCYTE CELLS, SEEMS TO BE AN HEPATOTROPHIC FACTOR, AND ACTS AS GROWTH FACTOR FOR A BROAD SPECTRUM OF TISSUES AND CELL TYPES. IT HS. NO DETECTABLE PROTEASE ACTIVITY.
C -!- SIMILARITY: HIGH. TO OTHER HGF; LOWER, TO PLASMINOGEN.
